

Project Idea submission

Recently, my friend and I decided to vacate our hostel and move into a separate room. However, one of my friend's father was not comfortable with this decision because he was worried about his son's safety outside the hostel environment. He felt that there would be no proper assurance or monitoring system to know whether his son was safe while living independently.

After discussing his concerns, I got the idea of building an AI-powered safety monitoring system. The main purpose of this system is to help parents feel more confident and reassured about their child's safety when they are living away from home.

The idea is to use home security cameras along with an AI-based vision model to identify and track a specific person. The system should be able to determine whether the person is inside or outside the room in real time. Whenever the system detects that the person has entered or left the room, it will automatically send a notification message to the parent along with the timestamp.

In addition to basic monitoring, the system can later be enhanced with intelligent features such as behavioral analysis, anomaly detection, and emergency alerts. The goal is not to create a surveillance system, but to develop an AI-powered safety assistant that provides peace of mind for parents while respecting user privacy and consent.
